Blade Design and Analysis for Steam Turbines

For most of those first 100 years, the analysis of turbine blades had concentrated on the behavior of individual blades. A key change, and one of the most significant advances in turbine reliability, was the development and application of analytical techniques that make it possible to characterize and explain the behavior not simply of individual turbine blades, but of entire bladed disk assemblies.

Blade design consists mainly of selecting the aerofoil section(s) that comprise the blade, and then determining the chord and twist distribution to optimise power output, for example. There are also localised structural and other requirements, such as the use of thick sections to ease the transition to circular blade attachments for large blades and chord modifications to reduce tip noise.

The use of probabilistic analysis in the design of wind turbine blades is a relatively new approach, with the first publications appearing during 1999 (see e.g. Braam et al., 1999). The recent works draw together the multidisciplinary advances that had taken place independently during the preceding 50 or 60 years, and embrace issues such as composite materials, their properties and the testing methods applied to them, as well as their modelling and behaviour prediction; wind turbine blades ...

An effective design of cutting blade for rotary lawn mower has been achieved. FLUENT analysis of the existing basic blade design produced a lot of undesirable turbulence resulting in poor channeling of grass to the collecting bag. These limitations was eliminated to a great extend in our final design.
